# Introduction

- Several decision-oriented approaches exist
  - Synthesis, V-Manage/ESI, Schmid&John, Kobra, etc.
- We have been developing the DOPLER approach for decision-oriented variability modelling
  - Supported by a set of tools
  - Validated with industry partner
- Motivation for this paper
  - More carefully define our modelling language (DoVML)
  - Understand and crystallize the differences between different decision-oriented approaches.

# DoVML Application Experiences

- Application domains and contexts
  - Deployment time configuration of steel plant automation (SME 07)
  - Runtime reconfiguration of service oriented systems (VAMOS 08)
  - Runtime adaptation of industrial automation systems (DSPL 08)
  - Configuration management of the DOPLER tool suite (ASE 08)
  - Personalization of enterprise resource planning systems (ICCBSS08)
- Different paradigms (SOC, CBD, IAS)
- Different assets (component, service, function block, ...)
- Different use (design time configuration, runtime adaptation)
- Significant model complexity, eg. Siemens VAI
  - 100+ decisions
  - 500+ artefacts
  - Complex dependencies

# Decisions in PLE

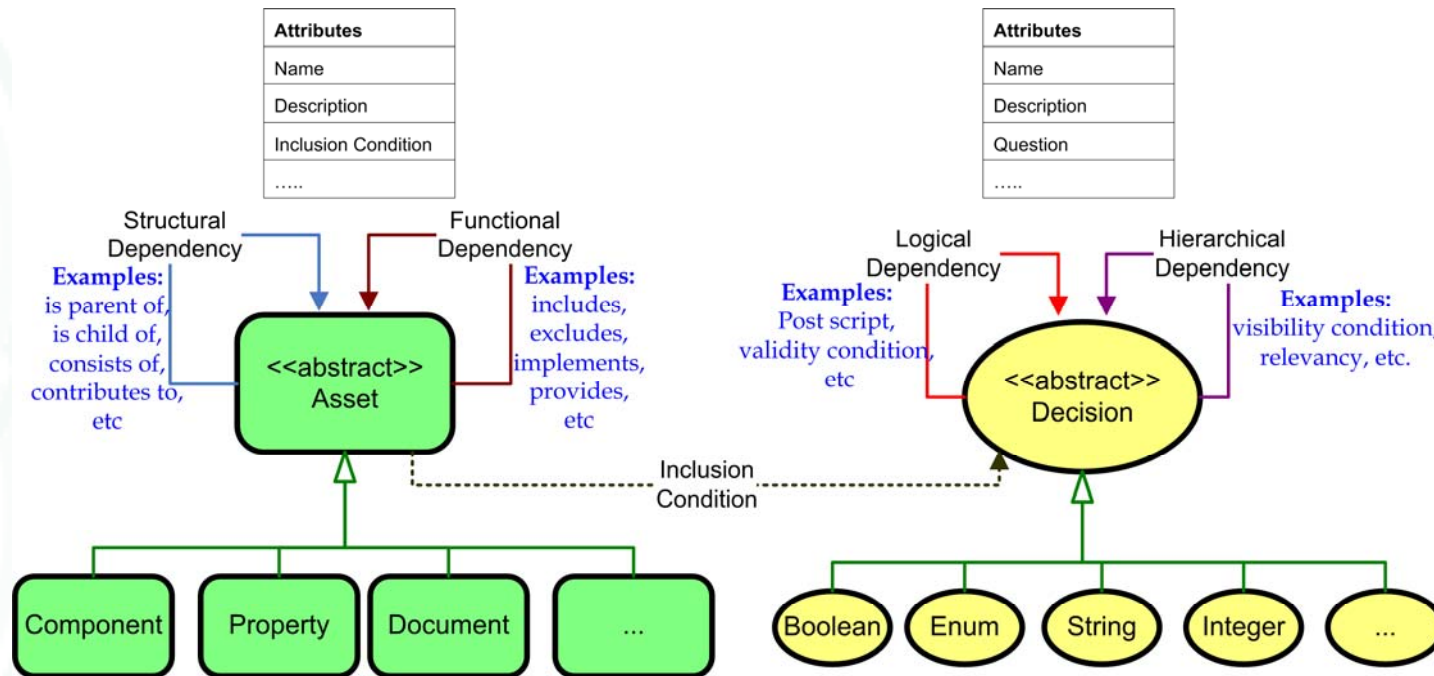

- Decision making is the process of judging the merits of multiple options and selecting one of them for action.
- Variability in PLE is also about choices, alternatives and decisions.
- In our modelling approach, **decisions** are **first class citizens** and not just add-ons to a general concept.
- A decision can represent
  - A step of configuration process
  - Variation points in the artefact space

# So, How Does it Work?

Variability modeling involves modeling the problem space and the solution space.

# Representing Decisions in a Model

- A decision can be compared to a typed variable in programming languages, enriched with
  - The set of possible values (including infinite sets, range constraints)
  - The specification of its position in the decision hierarchy (in relation to other available decisions)
  - The specification of the implications of taking the decision (on other decisions) and
  - Labels and annotations (information for the user to better understand the decision).

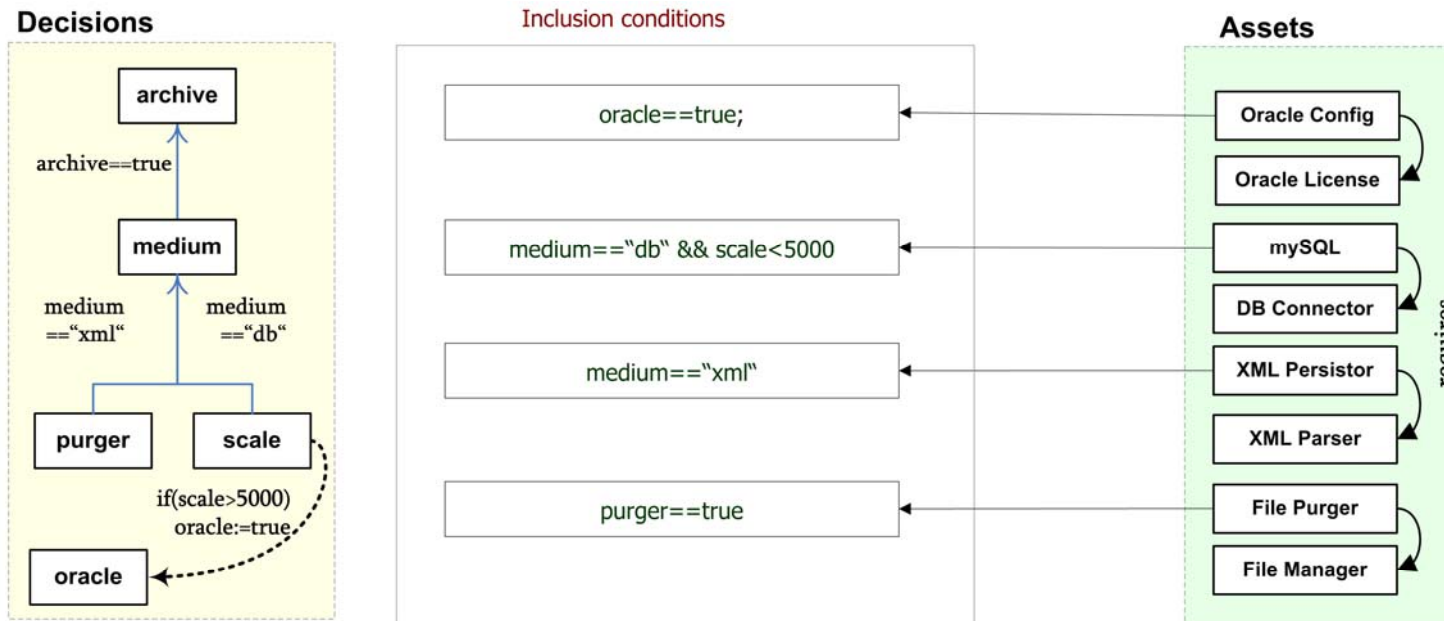

**Therefore, taking a decision is equivalent to binding a variable to a value.**

# Representing Assets in a Model

- Basically Boolean variables
  - Either included or excluded from the final product
  - Value determined by the inclusion condition
- Importance of Asset types
  - Enables domain-specific abstraction for the modeler
  - Component, Test case, .., Document, etc
- Importance of Asset dependencies
  - Not just decisions but also assets are related/dependent on each other
  - Enable domain-specific nomenclature for basic concepts
    - Parent, child, inclusion, exclusion, predecessor, successor, etc.

**Different domain-specific tools deal with the list of included assets and their dependencies to create/generate a customer-specific solution.**

# Example

## Partial declaration of decisions (Problem Space)

|   |
|---|
| Boolean decision <b>archive</b> visible if true;                          |
| Question: Do you want to archive daily records?                           |
| Enumeration decision <b>medium</b> visible if archive==true;              |
| Question: Which medium should be used for archiving records?              |
| Boolean decision <b>purger</b> visible if medium=="xml";                  |
| Question: Do you want old xml files to be automatically deleted?          |
| Integer decision <b>scale</b> visible if medium=="db"; valid if scale>=0; |
| Question: Enter the anticipated number of daily records!                  |
| Post-script: if(scale>5000) oracle:=true;                                 |
| Integer decision <b>oracle</b> visible if false;                          |
| // state variable, not visible to the user                                |

## Partial declaration of assets (Solution Space)

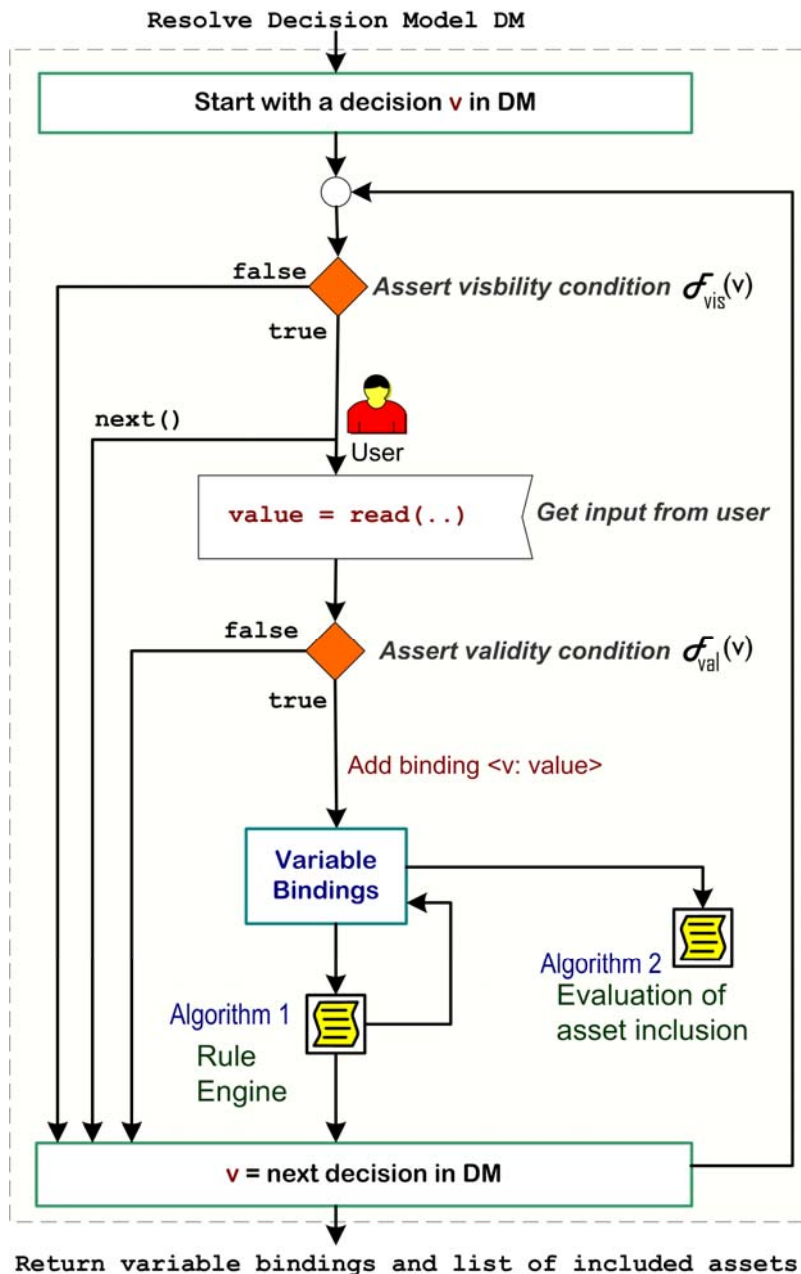

|  |                                 |
|--|---------------------------------|
| Component <b>XML Persistor</b> included if medium=="xml";      | requires {XML Parser}           |
| Component <b>MySQL</b> included if medium=="db" && scale<5000; | requires {DB Connector}         |
| Component <b>File Purger</b> included if purger==true;         | requires {File Manager}         |
| Component <b>Oracle Config</b> included if oracle==true;       | requires {Oracle Licence}       |
| Component <b>DB Connector</b> ;                                | Component <b>File Manager</b> ; |
| Component <b>Oracle Licence</b> ;                              | Component <b>XML Parser</b> ;   |

# You mean, you execute models?

- Our decision models can be interpreted (“executed”) by tools.
- Users are presented with the list of relevant questions.
- The model answers two basic questions
  - What were the options chosen by the user?
  - What assets are required to fulfil the choices?
- The model guarantees:
  - The options chosen by the user are consistent
  - The list of required assets is complete

# Executing a Decision Model

- Currently supported by our tool DecisionKing
  - Decision types: Boolean, Enumeration, String, Number
  - Asset dependency types: inclusion, exclusion, parent, child, predecessor, successor, abstraction, implementation, etc.
- Rule Engine is based on JBoss Engine
  - Custom rule language adding syntactic sugar to JBOSS Drools Rule Language

```

1 if (num_strands >4) then
2   setValue(casting_mode , { "Single" });
3 endif
  
```

is automatically translated into drools rule:

```

1 rule "0"
2   salience 0
3   no-loop true
4   when
5     num_strands : RuleNumberDecision (
6       name == "num_strands",
7       active == true ) and
8     eval ( num_strands . getPValue() > 4 ) then
9     ArrayList<String> drools_a ;
10    i . identify ();
11    drools_a = new ArrayList<String> ();
12    drools_a . add ( "Single" );
13    i . set ( 0 , "casting_mode",
14             new ArrayList<String> ( drools_a ) );
15  end
  
```

# Tools for Defining and Executing Decision Models

The image displays the DecisionKing software interface, which is used for defining and executing decision models. The interface is divided into several main sections:

- Decision Model Editor (Top Left):** Shows a tree view of decisions and placeholders. The 'num\_strands' decision is selected. The main area displays the configuration for 'num\_strands':
  - Name:** num\_strands
  - Question:** How many strands does the caster cast?
  - Default value:** 1.0
  - Description:** (empty)
  - Visibility condition:** `scope=="basis"`
  - Validity condition:** `num_strands > 0 && num_strands <= 8`
  - Rule:** `if num_strands > 4 then setValue(casterFromVai, 1.0)`
  - Allocation:** Group -
- Configuration Wizard (Bottom Left):** Shows a list of decisions to be configured, including 'HMI', 'Unassigned Decisions', and 'Required Assets'. The 'Unassigned Decisions' section is expanded, showing various questions related to the casting process, such as 'What is the scope of the product to be delivered?' and 'Which cooling model do you want to apply?'. The 'Required Assets' section lists various XML files used by the model.
- Decision King Web Interface (Top Right):** Shows the 'Decision King' logo and a questionnaire with 59 questions. The 'Implications (Required assets)' section lists the assets required for the current configuration, including various XML files like 'caster/caster.xml', 'caster/casterAlarms.xml', etc.
- Graphical View (Bottom Right):** Shows a graphical representation of the decision model, including a 'change style/orientation filter' button.

# Summary and Future Work

- DOVML consists of key modeling elements Decisions and Assets
- Tool support is required for
  - Specification of rules
  - Evaluation and execution of models
- We have applied the approach in a number of development contexts
  - Deployment time configuration of steel plant automation (SME 07)
  - Runtime reconfiguration of service oriented systems (VAMOS 08)
  - Runtime adaptation of industrial automation systems (DSPL 08)
  - Configuration management of the DOPLER tool suite (ASE 08)
  - Personalization of enterprise resource planning systems (ICCBSS 08)
- Ongoing Work
  - More formal representations of decision-oriented variability models and their formal semantics
  - Formal comparison of our approach with other decision-oriented approaches
  - Consistency checking and static analysis of decision models

# Questions? Now- or later!
